DESCRIPTION:   Setting: Urban Small town   Rural X		
Describe Setting:		
Bridge No. 6007 carries MD 31 (New Windsor Road) over Dickerson Run in Carroll County. MD 31 runs north-south and Dickerson Run flows east-west. The bridge is located in the vicinity of New Windsor and is surrounded by farmland.		
Describe Superstructure and Substructure:		
Bridge No. 6007 is a 1-span, 2-lane, concrete beam bridge. The bridge was originally built in 1924. The structure is 30 feet long and has a clear roadway width of 24 feet. The out-to-out width is 26 feet. The superstructure consists of five (5) concrete T-beams which support a concrete deck and concrete parapets. The beams measure 32 inches x 16 inches and are spaced approximately 6 feet apart. The slab, an integral part of the T-beam, measures 14 inches thick, and it has a bituminous wearing surface. The structure has solid panel parapets and the roadway approaches are straight and level with the bridge. The substructure has two (2) concrete abutments. There are four (4) flared wing walls, and the bridge has a sufficiency rating of 63.8.		
According to the 1995 inspection report, this structure is in fair condition with minor section loss, cracking, spalling, and scour. The asphalt wearing surface is in good condition with no defects. The parapets have surface erosion. The concrete beams have some spalls with exposed reinforcing bars. The backwalls of the abutments have spalling and cracking, and the wing walls have light vertical and diagonal cracking.		
Discuss Major Alterations		
Inspection reports from 1995 detail no alterations to the bridge.		
HISTORY:		
WHEN was the bridge built: 1924  This date is: Actual Estimated  Source of date: Plaque Design plans County bridge files/inspection form  Other: State Highway Administration bridge files/inspection form		
WHY was the bridge built?		
The bridge was constructed in response to the need for a more efficient transportation network and increased load capacity.		
WHO was the designer?		
Unknown		
WHO was the builder?		

Unknown

WHY was the bridge altered?

N/A

Was this bridge built as part of an organized bridge-building campaign?

This bridge may have National Register significance for its association with:

Unknown

#### **SURVEYOR/HISTORIAN ANALYSIS:**

A - Events	B- Person _			
C- Engineering/architect	ural character	X	•	
The bridge is eligible for the Nati	onal Register o	of Historic Dl	aces under Criterian C. as	

The bridge is eligible for the National Register of Historic Places under Criterion C, as a significant example of concrete beam construction. The structure has a high degree of integrity and retains such character-defining elements of the type as the concrete slab, longitudinal beams, solid panel parapets, abutments, and wing walls.

### Was the bridge constructed in response to significant events in Maryland or local history?

The earliest concrete beam bridges in the nation were deck girder spans that featured concrete slabs supported by a series of longitudinal concrete beams. This method of construction was conceptually quite similar to the traditional timber beam bridge which had found such widespread use both in Europe and in America. Developed early in the twentieth century, deck girder spans continued to be widely used in 1920 when noted bridge engineer Milo Ketchum wrote *The Design of Highway Bridges of Steel, Timber and Concrete* (Ketchum 1920).

Although visually similar to deck girder bridges, the T-beam span features a series of reinforced concrete beams that are integrated into the concrete slab, forming a monolithic mass appearing in cross section like a series of upper-case "T"s connected at the top. Thaddeus Hyatt is believed to have been the first to come upon the idea of the T-beam when he was studying reinforced concrete in the 1850s, but the first useful T-beam was developed by the Belgian Francois Hennebique at the turn of the present century (Lay 1992:293). The earliest references to T-beam bridges refer to the type as concrete slab and beam construction, a description that does not distinguish the T-beam design from the concrete deck girder. Henry G. Tyrrell was perhaps the first American bridge engineer to use the now standard term "T-beam" in his treatise *Concrete Bridges and Culverts*, published in 1909. Tyrrell commented that "it is permissible and good practice in designing small concrete beams which are united by slabs, to consider the effect of a portion of the floor slab and to proportion the beams as T-beams" (Tyrrell 1909:186).

By 1920, reinforced concrete, T-beam construction had found broad application in standardized bridge design across the United States. In his text, *The Design of Highway Bridges of Steel, Timber and Concrete*, Milo S. Ketchum included drawings of standard T-beam spans recommended by the U.S. Bureau of Public Roads as well as drawings of T-beam bridges built by state highway departments in Ohio, Michigan, Illinois, and Massachusetts (Ketchum 1920). By the 1930s the T-beam bridge was widely built in Maryland and Virginia.

Maryland's roads and bridge improvement programs mirrored economic cycles. The first road improvement of the State Roads Commission was a 7 year program, starting with the Commission's establishment in 1908 and ending in 1915. Due to World War I, the period from 1916-1920 was one of relative inactivity; only roads of first priority were built. Truck traffic resulting from war related factories and military installations generated new, heavy traffic unanticipated by the builders of the early road system. From 1920-1929, numerous highway improvements occurred in response to the

increase in Maryland motor vehicles from 103,000 in 1920 to 320,000 in 1929, with emphasis on the secondary system of feeder roads which moved traffic from the primary roads built before World War I. After World War I, Maryland's bridge system also was appraised as too narrow and structurally inadequate for the increasing traffic, with plans for an expanded bridge program to be handled by the Bridge Division, set up in 1920. In 1920 under Chapter 508 of the Acts of 1920 the State issued a bond of \$3,000,000.00 for road construction; the primary purpose of these monies was to meet the state obligations involving the construction of rural post roads. The secondary purpose of these monies was to fund (with an equal sum from the counties) the building of lateral roads. The number of hard surfaced roads on the state system grew from 2000 in 1920 to 3200 in 1930. By 1930, Maryland's primary system had been inadequate to the huge freight trucks and volume of passenger cars in use, with major improvements occurring in the late 1930's. Most improvements to local roads waited until the years after World War I.

In the early years, there was a need to replace the numerous single lane timber bridges. Walter Wilson Crosby, Chief Engineer, stated in 1906, "the general plan has been to replace these [wood bridges] with pipe culverts or concrete bridges and thus forever do away with the further expense of the maintenance of expensive and dangerous wooden structures." Within a few years, readily constructed standardized bridges of concrete were being built throughout the state.

In 1930, the roadway width for all standard plan bridges was increased to 27 feet in order to accommodate the increasing demands of automobile and truck traffic (State Roads Commission 1930). The range of span lengths remained the same, but there were some changes designed to increase the load bearing capacities. The reinforcing bars increased in thickness. Visually, the 1930 design can be distinguished from its predecessors by the pierced concrete railing that was introduced at this time.

In 1933, a new set of standard plans were introduced by the State Roads Commission. This time their preparation was not announced in the <u>Report</u>; new standard plans were by this time nothing special - they had indeed become standard. Once again accommodating the ever-increasing demands of traffic, the roadway was increased, this time to 30 feet. The slab span's reinforcing bars remained the same diameter but were placed closer together to achieve still more load capacity.

When the bridge was built and/or given a major alteration, did it have a significant impact on the growth and development of the area?

There is no evidence that the construction of this bridge had a significant impact on the growth and development of this area.

Is the bridge located in an area which may be eligible for historic designation and would the bridge add to or detract from the historic/visual character of the potential district?

The bridge is located in an area which does not appear to be eligible for historic designation.

Is the bridge a significant example of its type?

The bridge is a potentially significant example of a concrete beam bridge, possessing a high degree of integrity.

Does the bridge retain integrity of important elements described in Context Addendum?

The bridge retains the character-defining elements of its type, as defined by the Statewide Historic Bridge Context, including the concrete slab, longitudinal beams, parapets, abutments, and wing walls, however some deterioration is evident.

CARR-1557

Is the bridge a significant example of the work of a manufacturer, designer, and/or engineer?

This bridge is not a significant example of the work of a manufacturer, designer, and/or engineer.

Should the bridge be given further study before an evaluation of its significance is made?

No further study of this bridge is required to evaluate its significance.
